

Overview

Ethereum ETL lets you convert blockchain data into convenient formats like CSVs and relational databases.

With 1,700+ likes on GitHub, Ethereum ETL is the most popular open-source project for Ethereum data.

Data is available for you to query right away in [Google BigQuery](#).

Features

Easily export:

- Blocks
- Transactions
- ERC20 / ERC721 tokens
- Token transfers
- Receipts
- Logs
- Contracts
- Internal transactions (traces)

Advanced Features

- Stream blockchain data to Pub/Sub, Postgres, or other destinations in real-time
- Filter and transform data using flexible command-line options
- Support for multiple Ethereum node providers (Geth, Parity, Infura, etc.)
- Handles chain reorganizations through configurable lag
- Export data by block range or by date
- Scalable architecture with configurable batch sizes and worker counts

Use Cases

- Data analysis and visualization
- Machine learning on blockchain data
- Building analytics dashboards
- Market research and token analysis
- Compliance and audit reporting

- [Academic research on blockchain economics](#)

Projects using Ethereum ETL

- [Google](#) - Public BigQuery Ethereum datasets
- [Nansen](#) - Analytics platform for Ethereum
- [Ethereum Blockchain ETL on GCP](#) - Official Google Cloud reference architecture

Getting Started

Check the [Quickstart](#) guide to begin using Ethereum ETL or explore the [Commands](#) page for detailed usage instructions.
